Lab 3 Overview

PC Keyboard Operation: Data Input

Lab3: `kbd_test_scan()`

The KBC Commands

Keyboard Programming/Configuration

Lab 3: `kbd_test_poll()`

Lab 3: `kbd_test_timed_scan()`

Lab 3: The PC's Keyboard - Part 1

- ▶ Write functions:

```
int kbd_test_scan()  
int kbd_test_poll()
```

that require programming the PC's keyboard controller

- ▶ Compare the number of `sys_inb()` kernel calls
- ▶ These functions are not the kind of functions that you can reuse later in your project
 - ▶ The idea is that you design the lower level functions (with the final project in mind).
 - ▶ Reusable code should go on a different files from non-reusable code.
- ▶ What's new?
 - ▶ Program the KBC controller (i8042)
 - ▶ In part 2:
 - ▶ Handle interrupts from more than one device

Contents

Lab 3 Overview

PC Keyboard Operation: Data Input

Lab3: `kbd_test_scan()`

The KBC Commands

Keyboard Programming/Configuration

Lab 3: `kbd_test_poll()`

Lab 3: `kbd_test_timed_scan()`

PC Keyboard Operation: Data Input (1/2)

- ▶ The keyboard has its own controller chip (not shown): the controller@KBD (C@KBD)
- ▶ When a key is pressed the C@KBD generates a **scancode (make code)** and puts it in a buffer for sending to the PC
 - ▶ **Usually, a scancode is one byte long**
- ▶ The same happens when a key is released
 - ▶ Usually, the scancode when a key is released (**break code**) is the make code of that key with the MSB set to 1
- ▶ The communication between the C@KBD and the PC is via a serial line
 - ▶ I.e. the bits in a byte are sent one after the other over a pair of wires

PC Keyboard Operation: Data Input (2/2)

- ▶ On the PC side this communication is managed by the keyboard controller (KBC)
 - ▶ In modern PCs, the KBC is integrated in the motherboard chipset
- ▶ When **OUT_BUF** (@ port 0x60) is empty:
 1. The KBC signals that via the serial bus
 2. The C@KBD sends the byte at the head of its buffer to the KBC
 3. The KBC puts it in the **OUT_BUF**
 4. The KBC generates an interrupt by raising **IRQ1**

Contents

Lab 3 Overview

PC Keyboard Operation: Data Input

Lab3: `kbd_test_scan()`

The KBC Commands

Keyboard Programming/Configuration

Lab 3: `kbd_test_poll()`

Lab 3: `kbd_test_timed_scan()`

Lab 3: `kbd_test_scan()` (1/2)

What Prints the scancodes, both the **makecode** and the **breakcode**, read from the KBC

- ▶ Should terminate when it reads the **breakcode** of the `ESC` key:
`0x81`
- ▶ The first byte of two byte scancodes is usually `0xE0`
 - ▶ This applies to both make and break codes

How Need to subscribe the KBC interrupts

- ▶ Upon an interrupt, read the scancode from the `OUT_BUF`

Note There is no need to configure the KBC

- ▶ It is already initialized by Minix

Issue Minix already has an IH installed

- ▶ Must be disabled to prevent it from reading the `OUT_BUF` before your handler does it

Solution Use not only the `IRQ_REENABLE` but also the `IRQ_EXCLUSIVE` policy in `sys_irqsetpolicy()`, i.e. use `IRQ_REENABLE | IRQ_EXCLUSIVE`

Lab 3: `kbd_test_scan()` (2/2)

KBC interrupt subscription in exclusive mode;

`driver_receive()` loop (similar to that of lab 2)

Interrupt handler reads the bytes from the KBC's `OUT_BUF`

- ▶ Should read only **one byte per interrupt**
 - ▶ The communication between the keyboard and the KBC is too slow
- ▶ Should check whether there was some error (see below)
- ▶ Should not print the scancodes (not reusable)
- ▶ In the project, you may think about including the code that maps the scancodes to a character code
 - ▶ IH in Minix are usually out of the critical path
 - ▶ They are executed with interrupts enabled and after issuing the EOI command to the PIC
 - ▶ In many systems this may not be appropriate. For example, in Linux most DD break interrupt handling in two:
 - Top half which is in the critical path, and therefore does minimal processing
 - Bottom half which is not in the critical path

Lab 3: Counting the number of `sys_inb()` calls

Issue You do not want this feature in the project

Solution Use `#ifdef` for conditional compilation. Alternatives:

Use `#ifdef` before/after every `sys_inb()` / `util_sys_inb()` call

```
#define LAB3
sys_inb(...);
#ifdef LAB3
cnt++;
#endif
```

Use wrapper function `util_sys_inb()`

- ▶ You already call it instead of `sys_inb()`
- ▶ Need only to increment counter, if `LAB3` is defined

In both cases add line to Lab3's Makefile

```
CPPFLAGS += -D LAB3
```

Contents

Lab 3 Overview

PC Keyboard Operation: Data Input

Lab3: `kbd_test_scan()`

The KBC Commands

Keyboard Programming/Configuration

Lab 3: `kbd_test_poll()`

Lab 3: `kbd_test_timed_scan()`

The KBC Commands (of the PC-AT)

- ▶ The KBC added a few commands, the **KBC commands**, and two new registers at port 0x64

Status Register for reading the KBC state

Not named for writing KBC commands

- ▶ Apparently, this is not different from the `IN_BUF` at port 0x60
- ▶ The value of input line A2 is used by the KBC to distinguish KBC commands from KBD commands
- ▶ That is: the KBC has **only one** writable register, the `IN_BUF`

Status Register

- ▶ Both KBC's input and output require reading the status register

Bit	Name	Meaning (if set)
7	Parity	Parity error - invalid data
6	Timeout	Timeout error - invalid data
5	Aux	Mouse data
4	INH	Inhibit flag: 0 if keyboard is inhibited
3	A2	A2 input line: 0 data byte 1 command byte
2	SYS	System flag: 0 if system in power-on reset, 1 if system already initialized
1	IBF	Input buffer full don't write commands or arguments
0	OBF	Output buffer full - data available for reading

- ▶ Bits 7 and 6 signal an error in the serial communication line between the keyboard and the KBC
 - ▶ **Should check them in the IH**
- ▶ Do not write to the `IN_BUF`, if bit 1, i.e. the `IBF`, is set.

Keyboard-Related KBC Commands for PC-AT/PS2

- ▶ These commands must be written using address `0x64`
 - ▶ Arguments, if any, must be passed using address `0x60`
 - ▶ Return values, if any, are passed in the `OUT_BUF`

Command	Meaning	Args (A)/ Return (R)
<code>0x20</code>	Read Command Byte	Returns Command Byte
<code>0x60</code>	Write Command Byte	Takes A: Command Byte
<code>0xAA</code>	Check KBC (Self-test)	Returns <code>0x55</code> , if OK Returns <code>0xFC</code> , if error
<code>0xAB</code>	Check Keyboard Interface	Returns <code>0</code> , if OK
<code>0xAD</code>	Disable KBD Interface	
<code>0xAE</code>	Enable KBD Interface	

KBD Interface is the serial interface between the keyboard and the KBC

- ▶ Disabling of the KBD interface is achieved by driving the clock line low.
- ▶ There are several others related to the mouse

(KBC “Command Byte”)

7	6	5	4	3	2	1	0
–	–	DIS2	DIS	–	–	INT2	INT

DIS2 1: disable mouse

DIS 1: disable keyboard interface

INT2 1: enable interrupt on OBF, from mouse;

INT 1: enable interrupt on OBF, from keyboard

– : Either not used or not relevant for Lab

Read Use KBC command 0x20, which must be written to 0x64

- ▶ But the value of the “command byte” must be read from 0x60

Write Use KBC command 0x60, which must be written to 0x64

- ▶ But the new value of the “command byte” must be written to 0x60

Lab 3 Overview

PC Keyboard Operation: Data Input

Lab3: `kbd_test_scan()`

The KBC Commands

Keyboard Programming/Configuration

Lab 3: `kbd_test_poll()`

Lab 3: `kbd_test_timed_scan()`

Keyboard Programming/Configuration

Status Register @ address 0x64

- Read the KBC state

Input Buffer @ either address 0x64 or address 0x60. Can be used to **write**:

Commands to the KBC access via address 0x64;

Arguments of KBC commands access via address 0x60

Output Buffer @ address 0x60. Can be used to **read**:

Scandcodes both make and break, received from the keyboard;

Return values from KBC commands;

Note These addresses belong to the I/O address space

- Need to use IN/OUT assembly instructions or the library functions `sys_inb()` / `sys_outb()` of the kernel API

Issuing a Command to the KBC

```
#define STAT_REG      0x64
#define KBC_CMD_REG 0x64

while( 1 ) {
    sys_inb(STAT_REG, &stat); /* assuming it returns OK */
    /* loop while 8042 input buffer is not empty */
    if( (stat & IBF) == 0 ) {
        sys_outb(KBC_CMD_REG, cmd); /* no args command */
        return 0;
    }
    delay(WAIT_KBC);
}
```

Note 1 Cannot output to the 0x64 while the input buffer is full

Note 2 Code leaves the loop only when it succeeds to output the data to the 0x64

- To make your code resilient to failures in the KBC/keyboard, it should give up after “enough time” for the KBC to send a previous command/data to the KBD.

Reading Return Value/Data from the KBC

```
#define OUT_BUF 0x60

while( 1 ) {
    sys_inb(STAT_REG, &stat); /* assuming it returns OK */
    /* loop while 8042 output buffer is empty */
    if( stat & OBF ) {
        sys_inb(OUT_BUF, &data); /* assuming it returns OK */

        if ( (stat & (PAR_ERR | TO_ERR)) == 0 )
            return data;
        else
            return -1;
    }
    delay(WAIT_KBC);
}
```

Note 1 Code leaves the loop only upon some input from the OUT_BUF.

► It is not robust against failures in the KBC/keyboard

Note 2 Must mask IRQ1, otherwise the keyboard IH may run before we are able to read the OUT_BUF

KBC Programming Issues

Interrupts If the command has a response, and interrupts are enabled, the IH will “steal” them away from other code

- ▶ The simplest approach is to disable interrupts.

Timing KBD/KBC responses are not immediate.

- ▶ Code needs to wait for long enough, but not indefinitely

Concurrent Execution The C@KBD continuously scans the KBD and may send scancodes, while your code is writing commands to the KBC:

- ▶ How can you prevent accepting a scancode as a response to a command?
 - ▶ It is easier to solve this for KBC commands than for KBD commands.
 - ▶ Assume that all scancode bytes generated by the KBD are different from the KBD responses

Contents

Lab 3 Overview

PC Keyboard Operation: Data Input

Lab3: `kbd_test_scan()`

The KBC Commands

Keyboard Programming/Configuration

Lab 3: `kbd_test_poll()`

Lab 3: `kbd_test_timed_scan()`

Lab 3: `kbd_test_poll()`

What? Read the scan codes by polling

How? Keep polling the status register (`0x64`), and read the OB, if OBF is set and AUX is cleared

- ▶ The function `lcf_start()` already disables keyboard interrupts by the KBC (this also prevents Minix's keyboard IH from "stealing" the scan codes)
- ▶ Must enable interrupts by writing **command byte** before exiting
 - ▶ Must read the **command byte** before to ...

Hint Try to design a solution based on layers that allows you to issue any KBC command, not just command `0x20/0x60`

Bottom layer Functions that read/write the KBC registers. Deals with the details of the KBC HW interface. E.g.:

- ▶ Checks the `IBF` flag before writing

Top layer Functions to issue either KBC commands

- ▶ Knows about the commands and the protocol, writing parameters as necessary and waiting for responses

Contents

Lab 3 Overview

PC Keyboard Operation: Data Input

Lab3: `kbd_test_scan()`

The KBC Commands

Keyboard Programming/Configuration

Lab 3: `kbd_test_poll()`

Lab 3: `kbd_test_timed_scan()`

Lab 3: `kbd_test_timed_scan(uint8_t idle)`

What Similar to `kbd_test_scan()` except that process should terminate, upon:

either release of the ESC key

or after `idle` seconds, during which no scancode is received

How Must subscribe interrupts both of the keyboard and the timer/counter

► Must handle both interrupts in the "`driver_receive()` loop"

```
12:         switch (_ENDPOINT_P(msg.m_source)) {
13:             case HARDWARE: /* hardware interrupt notification */
14:                 if (msg.NOTIFY_ARG & irq_timer0) { /* subscribed interrupt
15:                     ... /* process timer0 interrupt request      */
16:                 }
17:                 if (msg.NOTIFY_ARG & irq_kbd) { /* subscribed interrupt */
18:                     ... /* process KBD interrupt request  */
19:                 }
20:                 break;
21:             default:
22:                 break; /* no other notifications expected: do nothing */
23:         }
```

► Must not change timer 0's configuration

Lab 3: Grading Criteria

SVN (5%) Whether or not your code is in the right place (under `lab3/`, of the repository's root)

- ▶ Also, evidence of incremental development approach

Execution (65%) Make sure you test your code thoroughly

Code (30%)

code organization reusable and non-reusable code in \neq files

layering the higher the layer, the less knowledge about the KBC/keyboard interface is required

handling keyboard responses consider also cases of HW failure

See also the criteria used in the code evaluation of lab 2.

Self-evaluation **Must fill Google form** (check the handout)
